Effect of gamma rays on...

the formation of a film on the surface whose reflection coefficient is similar to that of monoxide-coated (etched) germanium. This results in the occurrence of the characteristic negative photocurrent. Thus, the strong change of the diode characteristics is not only due to inhomogeneities of the crystal lattice but also to the conversion of the dioxide coating into monoxide. Since surface electrons are transferred to the monoxide coating, it is assumed that it is negatively charged by applying a voltage in the blocked direction. This results in the formation of holes in the surface-near layer that provide a channel for excess conductivity. Light absorption transmits the electrons from the acceptor levels to the conduction band of the coating, and from there, overcoming a potential barrier, to the volume of the germanium. The oxide coating is positively charged due to accumulation of bound holes, which reduces their concentration in the channel and, subsequently, the reverse current. This model permitted to find empirical formulas for the excess reverse current and for the photocurrent in a germanium diode. The transient characteristics of the diode were computed, experimentally verified, and graphically compared. They were found to agree fairly well. After applying a voltage, the reverse current increases, whereas it decreases.

TOPIC TAGS: turbine blade, turbine blade design, blade joint, negative allowance

ABSTRACT: The authors note that in order to increase the capacity of gas turbines, there must be a considerable lowering of the level of vibration of parts in the engine parts, particularly in the blades. In the case of the blades of the first stage of the turbine, this is achieved primarily through the use of larger negative allowances. Figure 1 illustrates this. A method is outlined for determining the negative allowance between flanges for certain design and operational conditions. A formula is given for the estimation of the stresses in the flanges. A formula is given for the estimation of the reduction of negative allowance between hard flanges.

Moscow.. Vyssheye tekhnicheskoye uchilishche

Mashiny i tekhnologiya obrabotki metallov davleniyem; sbornik statey
(Machines and Technology for Pressure Working of Metals; Collection
of Articles) Moscow, Mashgiz, 1957. 127 p. (Its: [Trudy]
vyp. 79) 5,000 copies printed.

Ed.: Zimin, A.I.; Ed. of Publishing House: Mezhova, V.A.; Tech. Ed.:
Matveyeva, Ye.N; Chief Ed. of Literature on Heavy Machine
Building [Mashgiz]: Golovin, S.Ya.

PURPOSE: This collection of articles is intended for workers in
scientific research institutes and for others connected
with forging and stamping.

COVERAGE: This book contains scientific transactions of the Moskovskoye
vyssheye tekhnicheskoye uchilishche im. N.E. Baumana (Moscow
Higher Technical School). Theoretical and experimental studies
of problems in designing forging machines and in the technology
of pressure working of metals are presented. The transactions

Card 1/5

Calculations for Strength (Cont.)

SOV/1377

PURPOSE: This collection of articles is intended for engineers and designers working in the field of machine construction, for research fellows, and scientific workers.

COVERAGE: The collection is an inter-vuz publication of transactions concerning strength problems. It contains original reports on calculations for a number of structures used in machine building and their components. Considerations are given to calculations of the columns of hydraulic presses, the nonlinear theory of spiral springs, problems in the calculation of rubber components, theoretical and experimental investigations of circular plates of constant and variable stiffness, investigations of conical shells and of stressed assemblies of machine components. Calculations in the elasto-plastic domain are represented by an investigation of forced fits of discs and the creep of operating turbine blades. Problems of contact in the case of impact and the stability theory of elastic systems "in general terms" are considered. There are 114 references, 99 of which are Soviet, 9 English, 4 German, 1 French, 1 Polish.

AUTHOR: Blinnik, S.I.

TITLE: Calculating stresses originating in press crosshead walls near the column fixing points

PERIODICAL: Kuznechno-shtampovochnoye proizvodstvo, no. 2, 1961, 23 - 25

TEXT: The strength and rigidity calculation of press crossheads is not sufficiently developed and only few empirical data are available. The present article deals with the strength of the crosshead walls at the spot where they butt against the bush. The subject is discussed in view of the TsBKM practice proving that cracks occur in the stretched spot of the crosshead walls near the bushes. The simplest design is considered, with symmetric position of columns in relation to the press cylinder. A force of $\frac{P_1}{4}$ acts on each bush (the stresses arising during the fitting are not considered) and only stresses in the crosshead walls near it are analyzed. The calculation diagram shows that a $P_1 = \frac{8}{\pi}$ force acts on each wall. The known problem of the theory of elasticity of a wedge under concentrated force applied to the apex is used to find the distribution law of stresses in the crosshead walls. A straight line (beam) (r) is trac-

Card 1/4

A161/A133

Calculating stresses ...

ed to some point (A) where stresses (σ_r) arise which can be determined according to A.M. Kats (Ref. 4: Teoriya uprugosti [The theory of elasticity], Gostekhizdat, 1956):

$$\sigma_r = -\frac{2P_1}{r} \left(\frac{\sin \gamma \sin \theta}{2\alpha - \sin 2\alpha} + \frac{\cos \gamma \cos \theta}{2\alpha + \sin 2\alpha} \right) \quad (1)$$

In the considered case, for a rectangular wedge, $\gamma = \alpha = 45^\circ$, and

$$\sigma_r = -\frac{P_1}{r} (2.5 \sin \theta + 0.55 \cos \theta) \quad (2)$$

Formula (2) applies to the compressed zone of the wedge. For the stretched zone the signs have to be reversed, i.e.:

$$\sigma_r = -\frac{P_1}{r} (2.5 \sin \theta - 0.55 \cos \theta). \quad (3)$$

The position of the neutral line will be found with equation (3) if we assume σ_r equal zero and solve the equation for θ_0 (where θ_0 is the angle taken counter-clockwise from the bisector to the neutral line. For a rectangular wedge $\theta_0 = 120^\circ 40'$. To calculate the stresses, P_1 in the formulas (2) and (3) must be replaced by $P_1 \frac{2}{8}$, and the wall thickness (δ) introduced into the denominator.

Card 2/4

S/182/61/000/002/005/009
A161/A133

Calculating stresses ...

The final form of the formulas (2) and (3) will be

$$\sigma_r = -\frac{P}{86r} (2.5 \sin \theta + 0.55 \cos \theta) \quad (2a)$$

$$\sigma_r = \frac{P}{86r} (2.5 \sin \theta - 0.55 \cos \theta) \quad (3a)$$

The θ value varies in the ranges

$$0 \leq \theta \leq 45^\circ$$

The maximum stresses (σ_r) in the stretched zone have to be calculated with the formula (3a) at $\theta = 45^\circ$. Then

$$\sigma_r = 1.95 \frac{P}{r\delta} \quad (4)$$

Distance (r) from the bush center (the assumed force application point) should be taken not less than half the bush diameter, and the crosshead wall thickness corresponding to this distance must be substituted into the formula (4). If a rib is used between the bush and the press cylinder, and it is placed symmetrically and has the same height as the crosshead - the force will be divided into three parts, and the stress in the crosshead walls will be 1.5 times lower. The wall thickness (δ) in the stretched zone is highest at $r = \frac{D}{2}$. At a given

Card 3/4

Calculating stresses ...

S/182/61/000/002/005/009
A161/A133

stress (σ_r) in the case of θ reducing to θ_0 and r increasing, as this is seen from formula (3a), the thickness (δ) will decrease gradually with the approach to the neutral line and the increasing distance from the wedge apex. This shows that crossheads ought to be designed with windows at (r) distance where stresses are considerably below the permissible one. But this problem cannot yet be solved, for in (r) distance close to the ribs connecting the crosshead walls mid with the cylinder, the stresses state in the walls will be different from the state assumed for the wedge. The strain measured in crosshead models shows that the suggested formulae are accurate within 10 - 15%. Thus it is possible to analyze the crosshead work at the bushes and to calculate the wall thickness. [Abstracter's note: Essentially full translation]. There are 6 figures and 4 Soviet-bicc references.

TITLE: The effect of an oscillating field on gyrocompass readings

SOURCE: IVUZ. Priborostroyeniye, v. 9, no. 5, 1966, 110-113

TOPIC TAGS: gyrocompass, navigation compass, error function, error correction, marine equipment/MGK gyrocompass

ABSTRACT: The effect of a ship's oscillating field on the precision of marine MGK-gyrocompass reading has been investigated. The single gyroscope compass had a hydraulic pendulum and a gyroscopic means of damping the oscillations of its main axis. The mathematical analysis of the compass operation was based on the use of generalized coordinates of the lifting angle of the main axis' northern end and the azimuthal deflection angle to the east of a sensitive cell. Proceeding from the simplified differential motion equations and neglecting second-order members, an equation for the precision of gyrocompass readings, dependent on the vibration of its point of support, was derived. As demonstrated by a curve showing the vibrational error of a given gyrocompass, the error is significant only within a narrow frequency range which is in the vicinity of the mutation-vibrations of the sensitive

cell. The absorption rating of the sensitive cell of a gyrocompass is of particular importance for marine gyrocompasses where resonance conditions may be present.

"Determination of the Components of the Altitudinal Deformational Fields of Natural Synoptic Periods," Meteorol. i gidrologiya, No 10, 1953, pp 33-36

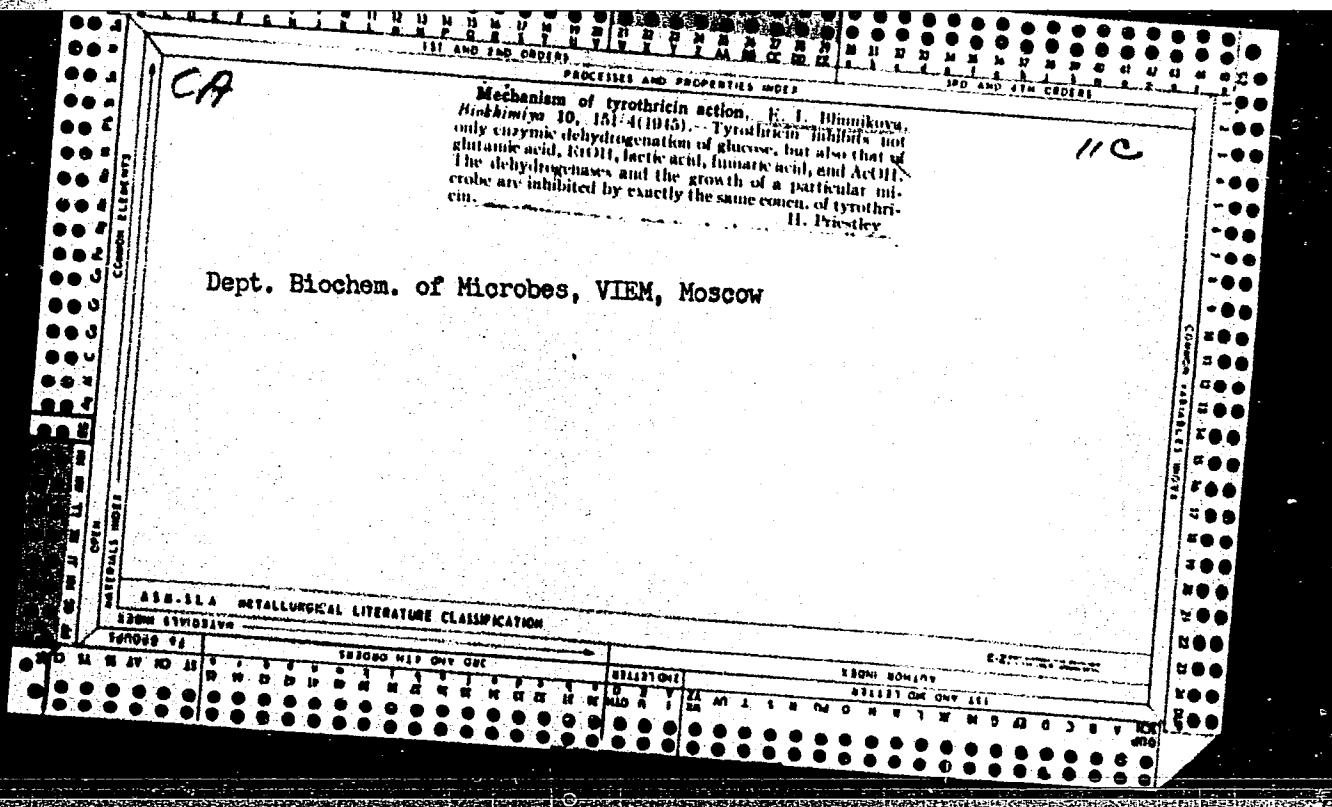

The altitudinal deformational field (ADF) characteristic for a natural synoptic period (NSP) is determined by its components: altitudinal cyclones and anticyclones which exist in the troposphere during the course of the entire NSP. During the disintegration of even one component of the ADF, or with the formation of a new component, a new NSP begins. The authors consider that the altitudinal cyclones and anticyclones traced on the chart AT 500 for the first days (tendency) of the NSP can be components of the ADF period if they correspond to independent thermal foci on the chart from 550/1000 of the same days. The authors investigate whether this condition is sufficient for the data of the altitudinal charts for 127 NSP 1951 and 1952. It turned out that only in 55-70% of all the NSP do the baric formations possessing, in the NSP tendency, independent thermal foci, exist in the course of the entire period. The indicated condition is thus a necessary but no sufficient criterion for the establishment of the components of ADF NSP. The authors found supplementary criteria establishing the relation between duration of existence of baric formations that possess in the tendency of the period independent thermal foci and their intensiveness in comparison with the baric relief surrounding them.
